

Thm: Let $\gamma: [a, b] \rightarrow \mathbb{R}^n$ be a rectifiable parametrized curve, & let

$$\begin{array}{ccc} & \tilde{\gamma} & \xrightarrow{\quad} \mathbb{R}^n \\ & \uparrow \gamma & \\ [c, d] & \xrightarrow{\quad \varphi \quad} & [a, b] \end{array}$$

be a parametrization of

γ . Then $\tilde{\gamma}$ is rectifiable strictly increasing + onto + ~~diff~~. Cont.

$\lim_{\|P\| \rightarrow 0} l(\gamma, P) \leftarrow l(\gamma) = l(\tilde{\gamma})$. (\Rightarrow parametrizations, as defined above, makes good sense.)

i.e.: length is invariant.

Proof: Let $\varepsilon > 0$. $\because \gamma$ is rectifiable, $\exists \delta > 0 \quad \text{s.t.}$

$$\left| \sum_{i=1}^n \|\gamma(t_i) - \gamma(t_{i-1})\| - \int_a^b \|\gamma'\| \right| < \varepsilon. \quad \text{--- (1)}$$

$$\forall P: a = t_0 < t_1 < \dots < t_n = b \quad \text{s.t.} \quad \|P\| < \delta,$$

$$\text{Also, } \exists \tilde{\delta} > 0 \quad \text{s.t.} \quad |\varphi(s) - \varphi(t)| < \delta \quad \forall |s - t| < \tilde{\delta}. \quad \text{--- (2)}$$

Note: $\tilde{\gamma} = \gamma \circ \varphi: [c, d] \rightarrow \mathbb{R}^n$.

By uniform continuity of φ .

Let \tilde{P} be a partition of $[c, d]$.

Set $\tilde{P}: c = s_0 < s_1 < \dots < s_m = b$.

$\because \varphi \uparrow$ onto: $P \in \mathcal{P}([a, b])$, where

$$P: a = \underbrace{t_0}_{\varphi(s_0)} < \underbrace{t_1}_{\varphi(s_1)} < \dots < \underbrace{s_m = b}_{\varphi(s_m)}$$

$$\text{Also } \sum_{i=1}^m \|\underbrace{\tilde{\gamma}(s_i)}_{\gamma(\varphi(s_i))} - \underbrace{\tilde{\gamma}(s_{i-1})}_{\gamma(\varphi(s_{i-1}))}\| = \sum_{i=1}^m \|\gamma(t_i) - \gamma(t_{i-1})\|.$$

& note that: if $\|\tilde{P}\| < \tilde{\delta} \Rightarrow \|P\| < \delta$ [by (2)]

$$\therefore (1) \Rightarrow \left| \sum_{i=1}^m \|\underbrace{\gamma(\varphi(s_i))}_{\tilde{\gamma}(s_i)} - \underbrace{\gamma(\varphi(s_{i-1}))}_{\tilde{\gamma}(s_{i-1})}\| - \int_a^b \|\gamma'\| \right| < \varepsilon.$$

$\Rightarrow \tilde{\gamma}$ is rectifiable &

$$l(\tilde{\gamma}) = \int_a^b \|\gamma'\| = l(\gamma). \quad \square$$

Remark: Usually, identification of rectifiable curve is not so easy.

See the notion of bounded variation. In fact: $\gamma = (\gamma_1, \dots, \gamma_n): [a, b] \rightarrow \mathbb{R}^n$ is rectifiable $\iff \gamma_i: [a, b] \rightarrow \mathbb{R}$ is of bounded variation $\forall i$.

A cool fact of "parametrizations":

Thm: Suppose $\gamma: [a, b] \rightarrow \mathbb{R}^n$ be a smooth curve. Then \exists a parametrization $\tilde{\gamma}$ of γ s.t.

$$\|\tilde{\gamma}'(s)\| = 1 \quad \forall s \in [c, d].$$

Here

$$\begin{array}{ccc} & \tilde{\gamma} & \uparrow \gamma \\ [c, d] & \xrightarrow{\varphi} & [a, b] \end{array}$$

The same route followed by the path with uniform (unit) speed!!

Proof:

So, we want φ , strictly increasing + onto + diff. s.t.

$$\tilde{\gamma} = \gamma \circ \varphi \quad \& \quad \|\tilde{\gamma}'(s)\| = 1.$$

If we have such φ , then

$$\tilde{\gamma}'(s) = \gamma'(\varphi(s)) \cdot \varphi'(s).$$

$$\& \quad 1 = \|\tilde{\gamma}'(s)\| = \|\gamma'(\varphi(s))\| |\varphi'(s)|$$

$$\Rightarrow |\varphi'(s)| = \frac{1}{\|\gamma'(\varphi(s))\|} \quad \leftarrow \text{This is what is expected!!}$$

$\varphi(s) = t$

~~So, if $\varphi'(s) > 0$, then~~

But $\varphi \uparrow \Rightarrow \varphi' > 0 \Rightarrow \varphi'(s) = \frac{1}{\|\gamma'(t)\|}$

~~\therefore The choice of φ is if $\tilde{\varphi}(t) := \int_a^t \|\gamma'\|$.~~

then $\tilde{\varphi}'(t) = \|\gamma'(t)\|$.

Set $\varphi(t) = \frac{1}{\tilde{\varphi}(t)}$ i.e. $\varphi(t) = \frac{1}{\int_a^t \|\gamma'\|}$

\therefore If we define $\varphi(t) = \frac{1}{\int_a^t \|\gamma'\|}$, then

$\tilde{\gamma} := \gamma \circ \varphi$ will have unit speed. Also, φ is a parametrization.

eg: $\gamma(t) := (t, 1-|t|)$. $t \in \mathbb{R}$.

$\therefore \gamma$ is not diff. at 0 $\Rightarrow \gamma$ is not ~~not~~ smooth at $t=0$.

Moreover, γ cannot be made smooth via any reparametrization. Consider a reparametrization:

$$\tilde{\gamma} = \gamma \circ \varphi$$

\nwarrow \uparrow , diff, onto.

Assume wlog: $\varphi(0) = 0$.

Now $\tilde{\gamma}(s) = \gamma(\varphi(s))$

$$\Rightarrow \tilde{\gamma}'(s) = \gamma'(\varphi(s)) \varphi'(s).$$

Trouble at $s=0$. As $\gamma'(0)$ is not defined.

In this case, γ has a corner at 0. \checkmark .

// i.e., a corner is a true non-smooth point, which cannot be reparametrized to a smooth curve.

— x —

eg: ① Consider $\gamma(t) = (\alpha t, \beta t - 16t^2)$. $\alpha, \beta \in \mathbb{R} \setminus \{0\}$.

$$\therefore \gamma'(t) = (\alpha, \beta - 32t).$$

eqn. of the trajectory of a thrown ball:

$$x = \alpha t, \quad y = \beta t - 16t^2.$$

$$\Rightarrow y = \frac{\beta}{\alpha} x - \frac{16}{\alpha^2} x^2.$$

$$\therefore L(\gamma) = \int \|\gamma'\|$$

$$= \int \sqrt{\alpha^2 + (\beta - 32t)^2} dt.$$

② Circumference of the Circle $x^2 + y^2 = r^2$.

Here: $\gamma(t) = (r \cos t, r \sin t)$. $0 \leq t \leq 2\pi$.

$$\therefore \gamma'(t) = (-r \sin t, r \cos t).$$

$$\therefore \|\gamma'(t)\|^2 = r^2 \Rightarrow \|\gamma'(t)\| = r \quad \forall t.$$

$$\therefore L(\gamma) = \int_0^{2\pi} r \, dt = 2\pi r.$$

Known fact: of course.

(3) Arc length of graphs: ~~more~~ Let $f: [a, b] \rightarrow \mathbb{R}$ be a C^1 -fn.
Define $\gamma(t) = (t, f(t))$. \leftarrow graph of f .

~~Then~~ Then $L(\gamma) = \int_a^b \sqrt{1 + \left(\frac{dy}{dx}\right)^2} \, dx.$ \leftarrow graph of f . $\left(y = f(x) \right).$

The familiar formula!!

Why? \leftarrow

~~At the same time~~ $\left[\because L(\gamma) = \int_a^b \sqrt{1^2 + \left(\frac{df}{dt}\right)^2} \, dt \right].$

Remark: We know $\text{Smooth} \Rightarrow \text{rectifiable} \Rightarrow$ Any reparametrization _{from} is also rectifiable & arc length remains invariant.

~~or piecewise smooth~~

So, in particular (see p-13): If $\tilde{\gamma}: [c, d] \rightarrow \mathbb{R}^n$ and $\gamma: [a, b] \rightarrow \mathbb{R}^n$ are reparametrizations of the same curve, then $L(\gamma) = L(\tilde{\gamma})$.

then $L(\gamma) = L(\tilde{\gamma})$ i.e. $\int_a^b \|\gamma'\| = \int_c^d \|\tilde{\gamma}'\|.$

Useful & minimum requirement.

Now, we define line integration:

Def: Let $f \in \text{Cont}(S)$ ^(\mathbb{R} -valued) & let $S = \text{ran } \gamma$, where $\gamma: [a, b] \rightarrow \mathbb{R}^n$ is a piecewise smooth parametrized curve. Then we define

$$\int_{\gamma} f = \int_a^b f(\gamma(t)) \|\gamma'(t)\| \, dt.$$

Line integrals (Some basic intro:)

Often scalar/vector fields are at least Cont: fr. i.e. all components are Cont.

Scalar field = scalar-valued fn line $f: \mathbb{R}^n \rightarrow \mathbb{R}$.
Vector field = vector-valued fn line $f: \mathbb{R}^n \rightarrow \mathbb{R}^n$.

A scalar field \Rightarrow a special vector field. Line:
 Let $f: \mathbb{R}^n \rightarrow \mathbb{R}$ be a scalar field & diff.
 Then ∇f is a vector field: (known as gradient field).]

Q: Given a scalar field $f: \mathbb{R}^n \rightarrow \mathbb{R}$, a bounded Curve $C \subseteq \mathbb{R}^n$, how to define $\int_C f$?
 $\sim \mathbb{Q}_n \subseteq \mathbb{R}^n$, or C w.r. to some parametrization.

$$\int_C f \quad ?$$

[One way: $\because C \subseteq \mathbb{R}^n$, we appeal to our ^{previous} integration theory & define $\int_C f = \int_{B^n} \tilde{f}$, $B^n \supseteq C$ a box!
the extension fr.

BUT, since $n \geq 1$, & C is a curve, C is of Content zero. $\Rightarrow \int_{B^n} \tilde{f} = 0 \Rightarrow \int_C f = 0$

\Rightarrow WRONG WAY!! — Not so desirable.]

Right way:

Def: Let $\gamma: [a, b] \rightarrow \mathbb{R}^n$ be a smooth curve, $C = \text{ran } \gamma$ (the path of γ) & let $f \in \mathcal{B}(C)$. [Note: $C \subseteq \mathbb{R}^n$].

Given $P: a = t_0 < t_1 < \dots < t_m = b$, a partition of $[a, b]$, define

$$U(f, P) = \sum_{i=1}^m M_i \delta_i \quad \& \quad L(f, P) = \sum_{i=1}^m m_i \delta_i, \text{ where}$$

$$\delta_i := \|\gamma([t_i, t_{i-1}])\|, \quad M_i := \sup_{C_i} f, \quad m_i := \inf_{C_i} f \quad \forall i=1, \dots, m.$$

Length \rightsquigarrow $C_i \subseteq \mathbb{R}^n$

We call $U(f, P) \rightarrow$ upper sum of f w.r.to P ($\mathcal{U}f$)

$L(f, P) \rightarrow$ lower $\rightarrow u$

Don't miss that:
 γ is here!!

$$[\|\gamma([t_{i-1}, t_i])\| \\ = \|\gamma(t_i) - \gamma(t_{i-1})\|.]$$

Def: Given a rectifiable (/ piecewise smooth) curve $\gamma: [a, b] \rightarrow \mathbb{R}^n$,
Set $C = \text{ran } \gamma$ (the path). We say $f \in \mathcal{B}(C)$ is
integrable if

$$\inf_{P \in \mathcal{P}[a, b]} \mathcal{U}f = \sup_{P \in \mathcal{P}[a, b]} \mathcal{L}f. \quad \text{--- } \otimes$$

In this case, the common value of the integration is
will be denoted by:

$$\int_C f ds.$$

↓
Called: line (or contour) integral.

The following is convincing: but the proof is left to you (it will
be slightly non-trivial but routine computation):

Thm: Let $\gamma: [a, b] \rightarrow \mathbb{R}^n$ be a rectifiable curve, $C = \text{ran } \gamma$ &
 $f \in \mathcal{B}(C)$. Then:

(1) $f \in \text{Cont}(C) \Rightarrow f$ is integrable (in the sense of line
integrals).

(2) f is line integrable $\Leftrightarrow \lim_{\|P\| \rightarrow 0} \sum_{i \in \Lambda(P), \eta_i \in C_i} f(\eta_i) S_i$ exists.
Tag set:

In this case, $\int_C f = \lim_{\|P\| \rightarrow 0} \left[\sum_{i \in \Lambda(P)} f(\eta_i) S_i \right].$

For you \Rightarrow (3) If γ is C^1 & $f \in \mathcal{R}(C)$ [in the sense of \otimes], then

$$\int_C f ds = \int_a^b f(\gamma(t)) \|\gamma'(t)\| dt.$$
